# Identifying codes in (random) geometric networks* 

Tobias Müller ${ }^{\dagger}$ Jean-Sébastien Sereni ${ }^{\ddagger}$

#### Abstract

It is important for networks built from wireless sensors technology to have a functional location detection system. Identifying codes, first introduced to model fault diagnosis of multi-processor systems [10], have recently proved to be useful to address this question $[17,16]$. We are interested in the situation where the area of communication of each sensor is modelled by a disk: thus we consider identifying codes for the class of unit disk graphs. Minimising the size of an identifying code is $\mathcal{N} \mathcal{P}$-complete even for bipartite graphs [6]. First, we improve this result by showing that the problem remains $\mathcal{N} \mathcal{P}$-complete for bipartite planar unit disk graphs. Then, we address the question of the existence of an identifying code for random unit disk graphs. From a practical point of view, this corresponds to the case when sensors are randomly thrown on a plane. We derive the probability that there exists an identifying code as a function of the radius of the disks. The results obtained are in sharp contrast with those concerning random graphs in the Erdős and Rényi model [8].

[^0]
## 1 Introduction

Identifying codes are used in several applications. They were first introduced for fault diagnosis of multi-processor systems [10], but they proved to be useful in other areas, in particular location detection in harsh environments [16, 17, 4, 18]. Our study is motivated by this last application. More precisely, wireless sensors technology makes it possible to install small devices in existing infrastructure that can form a network. An important issue for these networks to be efficient is a functional location detection system, i.e., the ability to determine the locations of other parties.

Many described systems are based on the concept of proximity-based detection, in which user location is provided by a nearest sensor (references include [19, 12, 9, 15]). As noted in [16], such systems are not designed for robustness. Toward this end, a novel framework using identifying codes is proposed in [16]. The zone to be covered is divided into a finite set of regions, each of which being represented by a single point within its boundary. Then, the points are mapped to the vertices of a graph, and an edge is added between two vertices if and only if the corresponding points in the physical systems are able to communicate. The problem is to determine the nodes on which to place and activate sensors, such that each node is within the communication range of a different set of sensors. In other words, we want each resolvable position to be covered by a unique set of sensors, which allows to identify it.

With this application in mind, an important issue is the fundamental case when the areas of communication of sensors are represented by disks of fixed radius. The obtained graph is then a unit disk graph: given a set $V$ of points in the plane and a distance threshold $r>0$, let $G(V, r)$ denote the following graph. The vertex set is $V$, and distinct vertices are joined by an edge whenever the Euclidean distance between them is less than $r$. Any graph isomorphic to such a graph is called a unit disk graph. A realisation, or an embedding, of a unit disk graph $G$ is a set $V$ of points in the plane along with a distance threshold $r$ such that $G(V, r) \simeq G$. Before going any further, let us formally define, in the graph terminology, identifying codes.

Given a graph $G=(V, E)$, let $\bar{N}(v)$ denote the closed neighbourhood of the vertex $v$, that is the set $\{u \in V: u v \in E\} \cup\{v\}$. A subset $C$ of $V$ is called a code. For every vertex $v \in V$, the shadow of $v$ on a code $C$ is $\operatorname{Sh}_{C}(v):=\bar{N}(v) \cap C$. A code $C$ is covering if and only if $\operatorname{Sh}_{C}(v) \neq \emptyset$ for every vertex $v \in V$. It is separating if and only if, for every pair of distinct vertices $(u, v), \operatorname{Sh}_{C}(u) \neq \mathrm{Sh}_{C}(v)$. A code which is covering and separating is called identifying.

It is not hard to see that a graph has an identifying code if and only if the closed neighbourhoods of any two vertices are distinct - if there are two vertices with the same closed neighbourhood, they clearly cannot be separated, and otherwise the whole set of vertices is an identifying code. Thus, determining whether a given graph admits an identifying code is easy. On the contrary, minimising the size of an identifying code in an arbitrary graph is $\mathcal{N} \mathcal{P}$-complete, even when restricted to bipartite graphs [6] - for $\mathcal{N} \mathcal{P}$-completeness results regarding directed graphs, consult [5].

In the next section, we strenghten this result by showing that minimising the size of an identifying code in an arbitrary unit disk graph is $\mathcal{N} \mathcal{P}$-complete, even when
restricted to bipartite planar unit disk graphs.
In the last section, we perform random analysis, by studying the existence of an identifying code in random unit disk graphs: consider a sequence of graphs $\left(G_{n}\right)_{n}$ obtained as follows. Points $X_{1}, X_{2}, \ldots, X_{n} \in \mathbb{R}^{2}$ are picked at random, i.i.d. according to some probability distribution $\nu$ on $\mathbb{R}^{2}$, and $G_{n}$ is the graph whose vertex set is $\left\{X_{1}, X_{2}, \ldots, X_{n}\right\}$, with an edge between two vertices if and only if the corresponding points lie at distance less than $r(n)$ in the plane, where we assume that $r(n)$ is a sequence of distances. In full generality, any choice of $\nu$ that has a bounded probability density function is allowed. However, we shall restrict ourself to the uniform distribution on $[0,1]^{2}$ for the sake of readibility. Yet, the results can be extended to other distribution, if needed. The reader is welcomed to consult [14] about random geometric graphs. We shall prove that no identifying codes exist for random unit disk graphs, that is the probability that $G_{n}$ has an identifying code tends to zero as $n$ tends to infinity. Notice that this behaviour completely differs from what happens with the Erdős-Rényi model for random graphs: as shown in [8], if $p$ and $1-p$ both are at least $\frac{4 \log \log n}{\log n}$, then almost every graph in $\mathcal{G}_{n, p}$ admits an identifying code, and the minimum size of such a code is equivalent to $\frac{2 \log n}{\log \left(1 /\left(p^{2}+(1-p)^{2}\right)\right)}$.

## 2 Complexity

Minimising the size of an identifying code is $\mathcal{N} \mathcal{P}$-complete for arbitrary bipartite graphs [6]. We extend this result to arbitrary planar bipartite unit disk graphs.

Theorem 1 The following problem is $\mathcal{N P}$-complete:
INSTANCE: A planar bipartite unit disk graph $G$ and a positive integer $k$. QUESTION: Does $G$ have an identifying code of size at most $k$ ?

As it will appear in the proof, the problem is $\mathcal{N} \mathcal{P}$-complete even if an embedding of the unit disk graph is given. This is important since determining whether an arbitrary graph is a unit disk graph is $\mathcal{N} \mathcal{P}$-complete [3].

So as to prove this theorem, we shall need two lemmas. Given a graph $G$, call an handle of $G$ any induced path of $G$ whose vertices all have degree two in $G$.

Lemma 2 Consider any graph $G$ with an handle $P:=v_{1} v_{2} \ldots v_{6 k}$ of order $6 k$ for a positive integer $k$. Denote by $x$ the neighbour of $v_{1}$ in $V(G) \backslash\left\{v_{2}\right\}$. Then, any identifying code $C$ of $G$ contains at least $3 k$ vertices of $P$. Moreover, if $C$ contains exactly $3 k$ of these vertices and if $v_{6 k} \in C$, then $x \in C$.

Proof: The proof is by induction on the positive integer $k$, the result being easily checked if $k=1$. So, suppose that the result is true for an integer $k-1 \geq 1$, and let us prove it for $k$. Let $P$ be an handle as in the statement of the lemma, and $C$ an identifying code of $G$. The vertices $v_{1}, v_{2}, \ldots, v_{6(k-1)}$ form an handle $P_{1}$ of $G$, and the vertices $v_{6(k-1)+1}, \ldots, v_{6 k}$ form an handle $P_{2}$ of order 6 (see Figure 1). By the induction hypothesis, $C$ contains at least $3(k-1)$ vertices of $P_{1}$. As the result is true when $k$ is one, $C$ contains at least three vertices of $P_{2}$. Therefore, $C$ contains

Figure 1: Decomposition of $P$ into $P_{1}$ and $P_{2}$ in the proof of Lemma 2.

Figure 2: The variable-gadget of order four.
at least $3 k$ vertices of $P$. Moreover, if $C$ contains exactly $3 k$ of these vertices, then it contains exactly $3(k-1)$ vertices of $P_{1}$ and three vertices of $P_{2}$. So, if in addition $v_{6 k} \in C$, then $v_{6(k-1)} \in C$, since it is the neighbour of $v_{6(k-1)+1}$ not in $P_{2}$. Now, using the induction hypothesis on $P_{1}$, we deduce that $x \in C$, as desired.

The next lemma deals with the property of a particular graph, called a variablegadget.

Definition 3 A variable-gadget of order $\eta$, see Figure 2 for an example, is the graph $K=(V, E)$ where

- $V:=P \cup N \cup R$ with

$$
\begin{aligned}
P & :=\left\{u_{1}, u_{2}, \ldots, u_{\eta}\right\} \\
N & :=\left\{v_{1}, v_{2}, \ldots, v_{\eta}\right\}, \text { and } \\
R & :=\left\{y_{1}, z_{1}, y_{2}, z_{2}, \ldots, y_{2 \eta}, z_{2 \eta}\right\}
\end{aligned}
$$

- $E:=E_{1} \cup E_{2} \cup E_{3}$ with

$$
\begin{aligned}
& E_{1}:=\left\{z_{2 i-1} u_{i}, 1 \leq i \leq \eta\right\} \cup\left\{z_{2 i-1} v_{i}, 1 \leq i \leq \eta\right\} \\
& E_{2}:=\left\{z_{2 i} u_{i+1}, 1 \leq i \leq \eta\right\} \cup\left\{z_{2 i} v_{i}, 1 \leq i \leq \eta\right\}, \text { and } \\
& E_{3}:=\left\{z_{i} y_{i}, 1 \leq i \leq 2 \eta\right\}
\end{aligned}
$$

Note that for $E_{2}$, we set $u_{\eta+1}:=u_{1}$.

Lemma 4 Consider a graph $G$ containing a variable-gadget $K$ as an induced subgraph. Suppose moreover that only the vertices of $P \cup N$ can have neighbours outside of $K$. Then, any identifying code $C$ of $G$ contains at least $3 \eta$ vertices of $K$. Moreover, if $C$ contains exactly $3 \eta$ vertices of $K$, then either $P \subset C$ and $N \cap C=\emptyset$, or $N \subset C$ and $P \cap C=\emptyset$.

Proof: Clearly, any identifying code $C$ of $G$ must contain, for every $i \in\{1,2, \ldots, 2 \eta\}$, at least one vertex among $y_{i}, z_{i}$ so as to cover $y_{i}$. We assert now that, for every $i \in\{1,2, \ldots, 2 \eta\}$, at least one neighbour of $z_{i}$ different from $y_{i}$ must belong to $C$. Otherwise, $z_{i}$ and $y_{i}$ are not separated, since the only vertices of $C$ in $\bar{N}\left(z_{i}\right)$ also belong to $\bar{N}\left(y_{i}\right)$. Hence, the number of vertices of $C$ in $K$ is at least $3 \eta$.

Suppose now that $C$ contains a vertex of $P$ and a vertex of $N$. Then, by the previous remark, observe that there must exist indices $i, j, k$ such that $u_{i} \in C, v_{j} \in C$ and $z_{k}$ is adjacent to both $u_{i}$ and $v_{j}$. Still by the previous assertion, there also exist an index $k^{\prime} \neq k$, together with indices $i^{\prime}, j^{\prime}$ such that $u_{i^{\prime}} \in C, v_{j^{\prime}} \in C$ and $z_{k^{\prime}}$ is adjacent to both $u_{i^{\prime}}$ and $v_{j^{\prime}}$ (hence, at least one of $i^{\prime}, j^{\prime}$ is different from $i$ and $j$ ). But then, the number of vertices of $C$ in $N \cup P$ must be at least $\eta+1$, which concludes the proof.

Proof of Theorem 1: Let us outline the proof before going into details. Consider an instance $I=(\varepsilon, X)$ of 3 -SAT, where $\varepsilon=\left(\mathcal{C}_{1}, \mathcal{C}_{2}, \ldots, \mathcal{C}_{m}\right)$ is a set of clauses over the set of variables $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$. We can associate to $I$ a bipartite graph $H$ constructed by taking vertex set $\varepsilon \cup X$ and edges $x_{i} C_{j} \in E(H)$ if either $x_{i} \in C_{j}$ or $\overline{x_{i}} \in C_{j}$. PLANAR 3-SAT is the 3-SAT problem for the class of all instances for which $H$ is planar. In [11], it is shown that PLANAR 3-SAT is $\mathcal{N P}$-complete. So, consider an instance $I$ of PLANAR 3-SAT.

First we shall compute, in polynomial-time, a particular embedding of $H$, socalled box-orthogonal embedding. Then, we construct from it a planar bipartite unit disk graph $G$ along with an embedding $\stackrel{H}{H}$, still in polynomial-time, which has an identifying code of size at most $f(\stackrel{\circ}{H})$ if and only if $I$ can be satisfied. As the function $f$, to be made precise later, is polynomially computable, this will yield the desired result.

A box-orthogonal embedding of $H$ is a planar embedding of $H$ such that each edge is represented by alternate horizontal and vertical line segments, and each vertex is represented by a (possibly degenerate) rectangle, called a box. All line segments, including those at the perimeter of a box, are assumed to lie on lines of the integer grid - see Figure 2. Each planar graph has such an embedding, and it can be computed in polynomial-time [7, 13]. Observe that, by sufficiently subdividing the grid, we can ensure enough space between edges for what follows.

Figure 3: Example of a box-orthogonal embedding.
First, remark that every vertex of degree at most four can indeed be represented by just a point, and not a (non-degenerated) rectangle: it suffices for this to arrange

Figure 4: Embedding of a variable-gadget around a box. The bold circles represent the vertices of $P \cup N$.
edges incident to this vertex, see Figure 5(a). Thus, we suppose now that all the vertices of $\varepsilon$ are represented by points.

We ensure that every vertex $x_{i} \in X$ is represented by a rectangle, sufficiently big so that a variable-gadget $K_{i}$ of order $m$ can be embedded on its perimeter, as shown in Figure 4.

The edges around a box $B_{i}$ are modified as shown in Figure $5(\mathrm{~b})$, so as to ensure that an edge coming from a vertex $\mathcal{C}_{j}$ reaches a vertex of $P_{i}$ if $x_{i} \in \mathcal{C}_{j}$, and a vertex of $N_{i}$ if $\overline{x_{i}} \in \mathcal{C}_{j}$. Note that, for each variable gadget $K_{i}$, only the vertices of $P_{i} \cup N_{i}$ can have neighbours outside of $K_{i}$, and each of them can have at most one such neighbour.

(a) Reducing vertices of $\varepsilon$ to points.

(b) Ensuring that each edge reaches a vertex of $P_{i}$ or $N_{i}$, as desired.

Figure 5: Modifications of the embedding of the edges of $H$.

Now, we compute the length of each edge, and we subdivide each edge by points with rational coordinates so that

- each edge contains a number of points which is a multiple of 6 ; and
- every two non-consecutive points on an edge are at distance at least $1+2 \nu$ for some fixed positive rational $\nu$.
All these points are added to the vertex set of the graph $G$ we are building. Notice that this step also can be done in polynomial-time.

Last, we add a neighbour $o_{j}$ to each vertex $\mathcal{C}_{j} \in \varepsilon$ (this does not prevent the graph from being a unit disk graph since the vertices of $\varepsilon$ had degree three). The obtained graph $G$ is a planar unit disk graph, a realisation $H$ being obtained from the planar
embedding we built by centring a disk of radius $1 / 2+\nu$ at each vertex. It is moreover bipartite: the following 2 -colouring of $G$ is clearly proper. Colour 1 the vertices of $\varepsilon$. In each variable-gadget, colour 1 the vertices of $P \cup N \cup\left\{y_{1}, y_{2}, \ldots, y_{2 \eta}\right\}$ and 2 the remaining vertices, i.e., $z_{1}, z_{2}, \ldots, z_{2 \eta}$. Last, for each path $P$, alternatively colour 1 and 2 its vertices such that the endvertex adjacent to a vertex of a variable-gadget is coloured 1 , and the other endvertex 2 - this is possible since each such path has even order.

We prove now that $I$ can be satisfied if and only if $G$ has a code of size at most $f(\dot{H})$, defined below. For each clause $\mathcal{C}_{j}$ three paths, denoted by $p_{j}^{i}$ for $i \in\{1,2,3\}$, join the vertex $\mathcal{C}_{j}$ to the corresponding literals. Let $\gamma_{j}^{i}$ be the number of internal vertices of the path $p_{j}^{i}$ - note that each $\gamma_{j}^{i}$ is of the form $6 s$ for some positive integer $s=s(i, j)$. Set

$$
f(\stackrel{\circ}{H}):=2 n m+m+\frac{1}{2} \sum_{j=1}^{m} \gamma_{j}^{1}+\gamma_{j}^{2}+\gamma_{j}^{3}
$$

Suppose first that $I$ can be satisfied, and let us construct an identifying code $C$ of size at most $f(\dot{H})$. For each variable $x_{i}$, the vertices of $P_{i}$ are added to $C$ if $x_{i}$ is true, and the vertices of $N_{i}$ are added to $C$ otherwise. We also add the vertices $z_{j}$ of $R_{i}$. So far we have $n \times 2 m$ vertices in $C$. Consider a path $p_{j}^{i}$ : its vertices are denoted by $x v_{1} v_{2} \ldots v_{6 k} \mathcal{C}_{j}$, so $x$ belongs to a variable-gadget. If the literal to which $x$ corresponds is true, then $x$ is in $C$ : we add to $C$ the vertices $v_{2 i}$ for $i \in\{1,2, \ldots, 3 k\}$. Otherwise, we add to $C$ the vertices $v_{2 i-1}$ for $i \in\{1,2, \ldots, 3 k\}$. Last, we add to $C$ the vertices $o_{j}$ for $j \in\{1,2, \ldots, m\}$. The obtained code $C$ has size $f(\stackrel{\circ}{H})$. Notice that every vertex $\mathcal{C}_{j}$ has at least one neighbour in $C$ different from $o_{j}$, since the clause $\mathcal{C}_{j}$ is satisfied. The code $C$ is an identifying code: all the vertices are covered. For every $j \in\{1,2, \ldots, m\}, \operatorname{Sh}_{C}\left(o_{j}\right)=\left\{o_{j}\right\}$, and the shadow of $\mathcal{C}_{j}$ on $C$ consists of $\left\{o_{j}\right\}$ and at least one other vertex. The other vertices are clearly separated.

Conversely, suppose that $G$ has an identifying code $C$ of size at most $f(\dot{H})$. By Lemmas 2 and $4, C$ contains at least $\gamma_{j}^{i} / 2$ internal vertices of $p_{j}^{i}$, and at least $2 m$ vertices in each variable-gadget. Moreover, $C$ must contain at least one vertex among $\mathcal{C}_{j}, o_{j}$ so as to cover $o_{j}$. Hence, the code $C$ contains exactly that number of vertices in each of the subgraphs mentioned. Also, by Lemma 4, for each variable-gadget $K_{i}$, either $N_{i} \subset C$ and $P_{i} \cap C=\emptyset$, or $P_{i} \subset C$ and $N_{i} \cap C=\emptyset$. In the former case, set the corresponding variable $x_{i}$ to false, and set it to true in the latter case. Consider now any clause $\mathcal{C}_{j}$ : we infer that at least one neighbour of $\mathcal{C}_{j}$ different from $o_{j}$ also belongs to $C$ (otherwise $C$ would not be separating $\mathcal{C}_{j}$ and $o_{j}$ ). Consider the path $p_{j}^{i}$ to which this vertex belongs: its internal vertices form an handle $v_{1} v_{2} \ldots v_{6 k}$ of $G$. The code $C$ contains exactly $\gamma_{j}^{i} / 2$ vertices of this handle, and $v_{6 k} \in C$. Therefore, the neighbour of $v_{1}$ different from $v_{2}$ also belongs to $C$, by Lemma 2. By the definition, this vertex belongs to $P_{i} \cup N_{i}$ for some variable-gadget $K_{i}$, and hence the corresponding literal is true. Thus, the clause $\mathcal{C}_{j}$ is satisfied.

## 3 Random unit disk graphs

### 3.1 Statement of results

In this section, we consider the random unit disk graph $G_{n}$ described in the Introduction. Furthermore, to simplify the computations we will make the toroïdal convention, i.e., we identify opposite edges on $[0,1]^{2}$ (making it into a torus). We shall prove the following theorem.
Theorem 5 The following hold for $G_{n}$ under the assumptions stated:

$$
\lim _{n \rightarrow \infty} \mathbb{P}\left(G_{n} \text { has an ID-code }\right)=\left\{\begin{array}{cl}
1 & \text { if } n r^{2} \ll n^{-1} \\
\exp \left[-\frac{\pi \lambda}{2}\right] & \text { if } n r^{2} \sim \lambda n^{-1}, \text { for some } \lambda>0 \\
0 & \text { if } n^{-1}<n r^{2} \ll 1 \\
\exp [-\mu(r)] & \text { if } 0<r<\frac{1}{2} \sqrt{2} \text { is fixed } \\
0 & \text { if } r \geq \frac{1}{2} \sqrt{2}
\end{array}\right.
$$

where for $0<r \leq \frac{1}{2}$, we set

$$
\mu(r):=\frac{\pi}{16 r^{2}}
$$

and for $\frac{1}{2}<r<\frac{1}{2} \sqrt{2}$, we set

$$
\begin{aligned}
\mu(r):= & \frac{1}{4 r^{2} \sin \left(\frac{\beta}{2}\right)^{2}}\left[\frac{\cos \left(\frac{\beta}{2}\right)}{\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)}-\frac{1}{2}\right] \\
& +\frac{1}{4 r^{2} \sin (\beta)}\left[\frac{2\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \tan \left(\frac{\beta}{4}\right)}{\left(1-\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)\right) \tan \left(\frac{\beta}{4}\right)^{2}}+1+\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right. \\
& \left.+\frac{2}{\sqrt{\sin (\beta)}} \arctan \left(\sqrt{\frac{\left(1-\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)\right)}{\left(1+\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right)}} \tan \left(\frac{\beta}{4}\right)\right)\right]
\end{aligned}
$$

with $\beta=\beta(r):=\frac{\pi}{2}-2 \arccos \left(\frac{1}{2 r}\right)$.
The expression for $\mu(r)$ when $r>\frac{1}{2}$ given in Theorem 5 can be rewritten in terms of $r$ using the relations

$$
\begin{align*}
& \cos \left(\frac{\beta}{2}\right)=\frac{1}{2} \sqrt{2}\left(\frac{1}{2 r}+\sqrt{1-\frac{1}{4 r^{2}}}\right),  \tag{1}\\
& \sin \left(\frac{\beta}{2}\right)=\frac{1}{2} \sqrt{2}\left(\frac{1}{2 r}-\sqrt{1-\frac{1}{4 r^{2}}}\right),
\end{align*}
$$

together with $\tan \left(\frac{\beta}{4}\right)=\sqrt{\frac{1-\cos \left(\frac{\beta}{2}\right)}{1+\cos \left(\frac{\beta}{2}\right)}}$. Unfortunately, it does not appear possible to obtain a substantially simpler expression.

Notice that the toroïdal convention does not affect the conclusion of Theorem 5 in the cases when $r \rightarrow 0$, and that for $r \leq \frac{1}{4}$ the probability that $G_{n}$ has an identifying code without the toroïdal assumption is no more than the probability with the toroïdal assumption (so that for the case of fixed $r$ the theorem provides an upper bound).

Figure 6: The (asymptotic) probability that an identifying code exists as a function of $r$, for $r$ fixed.

### 3.2 Proofs

Let us say that vertices $X_{i}, X_{j}(j \neq i)$ of $G_{n}$ form a bad pair if $C\left(X_{i}\right) \Delta C\left(X_{j}\right)=\emptyset$, where $\Delta$ denotes the symmetric difference and $C$ denotes the closed neighbourhood (i.e., $C(v)=N(v) \cup\{v\}$ ). Let $Z$ denote the number of bad pairs in $G_{n}$. Thus

$$
\begin{equation*}
\mathbb{P}\left(G_{n} \text { has an ID-code }\right)=\mathbb{P}(Z=0) \tag{2}
\end{equation*}
$$

The very first assertion of Theorem 5 is rather trivial.
Lemma 6 If $n r^{2} \ll n^{-1}$ then $\mathbb{P}(Z=0)=1+o(1)$.
Proof: Notice that if $G_{n}$ contains no edges at all then the whole set of vertices is an identifying code. Let $Y:=\left|E\left(G_{n}\right)\right|$ be the number of edges of $G_{n}$. We see that

$$
\mathbb{E} Y \leq\binom{ n}{2} \pi r^{2}=o(1)
$$

So $\left|E\left(G_{n}\right)\right|=0$ with probability $1+o(1)$ and we are done.
Our next aim is to prove the theorem for $r$ in the range $n r^{2} \sim \frac{\lambda}{n}$. For this purpose we will use the following theorem by Penrose [14]. Originally it was phrased for arbitrary dimension $d$ and any absolutely continuous probability distribution, but we have taken $d=2$ and the uniform distribution on $[0,1]^{2}$ here.

Theorem 7 (Penrose) Let $k \in \mathbb{N}$ and suppose $\left(n r^{2}\right)^{k} \sim \lambda n^{-1}$ for some $\lambda>0$. Then

$$
\begin{aligned}
\lim _{n \rightarrow \infty} \mathbb{P}\left(\Delta\left(G_{n}\right)=k-1\right) & =1-\lim _{n \rightarrow \infty} \mathbb{P}\left(\Delta\left(G_{n}\right)=k\right) \\
& =\exp \left[-\frac{\lambda}{(k+1)!} \int_{\left(\mathbb{R}^{2}\right)^{k}} h_{k}\left(\left\{0, x_{1}, \ldots, x_{k}\right\}\right) \mathrm{d} x_{1} \ldots \mathrm{~d} x_{k}\right]
\end{aligned}
$$

where $h_{k}(A)$ equals one if $\Delta(G(A, r)) \geq k$ and zero otherwise.
This result allows us to give a short proof of the following statement,
Lemma 8 If $n r^{2} \sim \frac{\lambda}{n}$ then $\mathbb{P}(Z=0) \rightarrow e^{-\frac{\pi \lambda}{2}}$.
Proof: We first claim that whp. there are no components of order at least three. To see this, let $W$ be the collection of all 3-tuples $\left(X_{i_{1}}, X_{i_{2}}, X_{i_{3}}\right) \in\left\{X_{1}, \ldots, X_{n}\right\}^{3}$ with $i_{1}, i_{2}, i_{3}$ distinct and $\left\|X_{i_{1}}-X_{i_{2}}\right\|,\left\|X_{i_{1}}-X_{i_{3}}\right\|<r$. Then

$$
\mathbb{E} W=n(n-1)(n-2)\left(\pi r^{2}\right)^{2}=O\left(n^{-1}\right)
$$

So whp. $G_{n}$ consists of components of size at most two (i.e., isolated vertices and isolated edges) and it follows that

$$
\mathbb{P}(Z=0)=\mathbb{P}\left(\Delta\left(G_{n}\right)=0\right)+o(1)
$$

Now applying Theorem 7 with $k=1$ yields the result, since $\int_{\mathbb{R}^{2}} h_{1}(\{0, x\}) \mathrm{d} x=\pi$.

For convenience, we will split the case when $n r^{2} \gg n^{-1}$ and $r=o(1)$ into two subcases (that require/allow different proof techniques).

Lemma 9 If $n^{-1} \ll n r^{2} \ll \ln n$ then $\mathbb{P}(Z=0)=o(1)$.
Proof: Denote by $Y$ the number of isolated edges. For convenience, let us write $V_{r}\left(a_{1}, \ldots, a_{l}\right):=\operatorname{vol}\left(\cup_{i=1}^{l} B\left(a_{i}, r\right)\right)$ for $a_{1}, \ldots, a_{l} \in \mathbb{R}^{2}$ and $l \geq 1$. Then

$$
\begin{equation*}
\mathbb{E} Y=\binom{n}{2} \int_{[0,1]^{2}} \int_{B(x, r)}\left(1-V_{r}(x, y)\right)^{n-2} \mathrm{~d} y \mathrm{~d} x \tag{3}
\end{equation*}
$$

Notice that $\pi r^{2} \leq V_{r}(x, y) \leq 2 \pi r^{2}$. Because $\ln (1-x)=-x+O\left(x^{2}\right)$ and $r=o(1)$ we see that

$$
\begin{equation*}
\binom{n}{2} \pi r^{2} e^{-(2 \pi+o(1)) n r^{2}} \leq \mathbb{E} Y \leq\binom{ n}{2} \pi r^{2} e^{-(\pi+o(1)) n r^{2}} \tag{4}
\end{equation*}
$$

So we can write $\mathbb{E} Y \geq(n-1) n r^{2} e^{-3 \pi n r^{2}}$ (for $n$ sufficiently large). The function $x e^{-3 \pi x}$ is increasing for $x \leq(3 \pi)^{-1}$ and decreasing for $x \geq(3 \pi)^{-1}$. Thus, for $(3 \pi)^{-1} \leq n r^{2} \ll \ln n$, we have $\mathbb{E} Y \geq(n-1)(3 \pi)^{-1} e^{o(\ln n)}=n^{1+o(1)}$. For $n^{-1} \ll$ $n r^{2} \leq(3 \pi)^{-1}$, we have $\mathbb{E} Y \geq(n-1) \frac{a(n)}{n} e^{o(1)} \sim a(n)$ where $a(n) \gg 1$ is such that $n r^{2} \gg \frac{a(n)}{n}$. In particular, $\mathbb{E} Y \rightarrow \infty$.
We now claim that

$$
\begin{equation*}
\operatorname{Var}(Y)=o\left((\mathbb{E} Y)^{2}\right) \tag{5}
\end{equation*}
$$

From this the statement will follow, because Chebyschev's inequality then gives:

$$
\mathbb{P}(Z=0) \leq \mathbb{P}(Y=0) \leq \mathbb{P}(|Y-\mathbb{E} Y| \geq \mathbb{E} Y) \leq \frac{\operatorname{Var}(Y)}{(\mathbb{E} Y)^{2}}=o(1)
$$

Thus it only remains to prove (5). Notice that

$$
\begin{aligned}
(\mathbb{E} Y)^{2} & =\left(\binom{n}{2} \int_{[0,1]^{2}} \int_{B(x, r)}\left(1-V_{r}(x, y)\right)^{n-2} \mathrm{~d} y \mathrm{~d} x\right)^{2} \\
& =\binom{n}{2}^{2} \iiint \int_{A}\left(1-V_{r}\left(x_{1}, y_{1}\right)\right)^{n-2}\left(1-V_{r}\left(x_{2}, y_{2}\right)\right)^{n-2} \mathrm{~d} y_{2} \mathrm{~d} x_{2} \mathrm{~d} y_{1} \mathrm{~d} x_{1}
\end{aligned}
$$

where $A$ is the set of all $\left(x_{1}, y_{1}, x_{2}, y_{2}\right) \in\left([0,1]^{2}\right)^{4}$ with $y_{1} \in B\left(x_{1}, r\right), y_{2} \in B\left(x_{2}, r\right)$. Let us set $\mathcal{P}:=\binom{[n]}{2}$ and for $P=\{i, j\} \in \mathcal{P}$ denote by $I(P)$ the indicator variable of the event that $\left\{X_{i}, X_{j}\right\}$ spans an isolated edge. We have

$$
\begin{aligned}
Y^{2} & =\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=2}} I\left(P_{1}\right) I\left(P_{2}\right)+\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} P_{2}\right|=1}} I\left(P_{1}\right) I\left(P_{2}\right)+\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=0}} I\left(P_{1}\right) I\left(P_{2}\right) \\
& =\sum_{P \in \mathcal{P}} I\left(P_{1}\right)+\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=0}} I\left(P_{1}\right) I\left(P_{2}\right) .
\end{aligned}
$$

Here we have used that $I \in\{0,1\}$ and two isolated edges cannot meet in a single vertex. Thus,

$$
\begin{equation*}
\mathbb{E} Y^{2}=\mathbb{E} Y+\binom{n}{2}\binom{n-2}{2} \iiint \int_{A_{0}}\left(1-V_{r}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)\right)^{n-4} \mathrm{~d} y_{2} \mathrm{~d} x_{2} \mathrm{~d} y_{1} \mathrm{~d} x_{1} \tag{6}
\end{equation*}
$$

where $A_{0}$ is the set of all $\left(x_{1}, y_{1}, x_{2}, y_{2}\right) \in A$ with $x_{2}, y_{2} \notin B\left(x_{1}, r\right) \cup B\left(y_{1}, r\right)$. Let $A_{1}$ be the set of all $\left(x_{1}, y_{1}, x_{2}, y_{2}\right) \in A_{0}$ with $\left\|x_{1}-x_{2}\right\| \geq 4 r$ and set $A_{2}:=A_{0} \backslash A_{1}$. Observe that for $\left(x_{1}, y_{1}, x_{2}, y_{2}\right) \in A_{1}$ holds $V_{r}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)=V_{r}\left(x_{1}, y_{1}\right)+V_{r}\left(x_{2}, y_{2}\right)$. Hence,

$$
\left(1-V_{r}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)\right)^{n-4} \leq\left(1-2 \pi r^{2}\right)^{-4}\left(1-V_{r}\left(x_{1}, y_{1}\right)\right)^{n-2}\left(1-V_{r}\left(x_{2}, y_{2}\right)\right)^{n-2}
$$

This shows that

$$
\begin{gathered}
\binom{n}{2}\binom{n-2}{2} \iiint \int_{A_{1}}\left(1-V_{r}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)\right)^{n-4} \mathrm{~d} y_{2} \mathrm{~d} x_{2} \mathrm{~d} y_{1} \mathrm{~d} x_{1} \\
\leq \\
\left(1-\pi r^{2}\right)^{-4}\binom{n}{2}^{2} \iiint \int_{A}\left(\left(1-V_{r}\left(x_{1}, y_{1}\right)\right)\left(1-V_{r}\left(x_{2}, y_{2}\right)\right)^{n-2} \mathrm{~d} y_{2} \mathrm{~d} x_{2} \mathrm{~d} y_{1} \mathrm{~d} x_{1}\right. \\
= \\
(1+o(1))(\mathbb{E} Y)^{2}
\end{gathered}
$$

And we see that

$$
\begin{aligned}
\operatorname{Var}(Y)= & \mathbb{E} Y^{2}-(\mathbb{E} Y)^{2} \\
\leq & \mathbb{E} Y+(1+o(1))(\mathbb{E} Y)^{2} \\
& +\binom{n}{2}\binom{n-2}{2} \iiint \int_{A_{2}}\left(1-V_{r}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)\right)^{n-4} \mathrm{~d} y_{2} \mathrm{~d} x_{2} \mathrm{~d} y_{1} \mathrm{~d} x_{1}-(\mathbb{E} Y)^{2} \\
= & o\left((\mathbb{E} Y)^{2}\right)+O\left(n^{4} r^{6} e^{-\pi n r^{2}}\right) .
\end{aligned}
$$

Here we have used that $\mathbb{E} Y=o\left((\mathbb{E} Y)^{2}\right)$ because $\mathbb{E} Y \rightarrow \infty$ in the last line. By a remark following (4) we get $n^{4} r^{6} e^{-\pi n r^{2}} /(\mathbb{E} Y)^{2}=O\left(r^{2} e^{5 \pi n r^{2}}\right)$. Recall that $n r^{2} \ll \ln n$ and note that $x e^{5 \pi x}$ is increasing, so that we can write $r^{2} e^{5 \pi n r^{2}}=\frac{1}{n} \cdot\left(n r^{2}\right) e^{5 \pi\left(n r^{2}\right)} \leq$ $n^{-1+o(1)}$. So (5) follows and we are done.

Lemma 10 If $n r^{2} \rightarrow \infty$ yet $r=o(1)$ then $\mathbb{P}(Z=0)=o(1)$.
The lemma will follow from the the following two lemmas together with the inequality $\mathbb{P}(Z=0) \leq \frac{\operatorname{Var}(Z)}{(\mathbb{E} Z)^{2}}$.

Lemma 11 If $n r^{2} \rightarrow \infty$ and $r<\frac{1}{2} \sqrt{2}-\epsilon$ for some $\epsilon>0$ then

$$
\mathbb{E} Z=(1+o(1)) \mu(r)
$$

Lemma 12 If $n r^{2} \rightarrow \infty$ and $r=o(1)$ then $\operatorname{Var}(Z)=o\left(r^{-4}\right)$.
Before we can give the proof of these last two lemmas, we need to do some more ground work. Denote by $D_{r}(x, y)$ the area of the symmetric difference $B(x, r) \Delta B(y, r)$. This difference only depends on $\|y-x\|$ and the angle between $y-x$ and the line $\{(a, a): a \in \mathbb{R}\}$. By a slight abuse of notation, we will also write $D_{r}(u, \alpha)$ for $D_{r}(x, y)$ if $u=\|y-x\|$ and $\alpha$ is the angle between $y-x$ and the line $\{(a, a): a \in \mathbb{R}\}$. The computations below will make use of the following lemma.

Lemma 13 If $0<r<\frac{1}{2}$ then

$$
D_{r}(u, \alpha)=4 u r+O\left(u^{2}\right) .
$$

If $\frac{1}{2} \leq r<\frac{1}{2} \sqrt{2}$ then

$$
D_{r}(u, \alpha)= \begin{cases}4 u r \sin \left(\frac{\beta}{2}\right)(\cos (\alpha)-\sin (\alpha))+o(u) & \text { if } \quad-\frac{\pi}{4} \leq \alpha<-\frac{\beta}{2} \\ 4 u r\left(1-\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \cos (\alpha)\right)+o(u) & \text { if } \quad-\frac{\beta}{2} \leq \alpha \leq 0 .\end{cases}
$$

Here $\beta=\beta(r)=\frac{\pi}{2}-2 \arccos \left(\frac{1}{2 r}\right)$ as before. Furthermore, the error terms $O\left(u^{2}\right)$ and $o(u)$, respectively, can be bounded uniformly in $\alpha$.

Proof: We need to consider the area $D_{r}(u, \alpha)=\operatorname{vol}(B(x, r) \Delta B(y, r))$ for $x, y$ with $\|x-y\|=u$ and the angle between $y-x$ and the diagonal $\left\{(a, a)^{T}: a \in \mathbb{R}\right\}$ is $\alpha$. For ease of computation, let us work with $\left[-\frac{1}{2}, \frac{1}{2}\right]^{2}$ instead of $[0,1]^{2}$ in this proof, and notice that by symmetry we may assume $x=(0,0)^{T}$ is the center of the unit square. Let $v_{\alpha}:=\left(\cos \left(\frac{\pi}{4}+\alpha\right), \sin \left(\frac{\pi}{4}+\alpha\right)\right)^{T}$ be a unit vector that makes an angle $\alpha$ with the diagonal of the unit square. Let $w_{\alpha}:=\left(\cos \left(\frac{3 \pi}{4}+\alpha\right), \sin \left(\frac{3 \pi}{4}+\alpha\right)\right)^{T}$ be a unit vector that is perpendicular to $v_{\alpha}$. First, consider $0<r<\frac{1}{2}$. In this case, for $u$ small enough, $B(x, r) \Delta B(y, r)$ lies completely in the interior of the unit square (so there are no effects due to the toroïdal assumption). Denote the boundary of $B(x, r)$ by $S$, and set $H_{\alpha}(c):=\left\{p: p \cdot w_{\alpha}=c\right\}$. Hence, $H_{\alpha}(c)$ is a line parallel to $v_{\alpha}$. We
will approximate $D_{r}(u, \alpha)$ by $\operatorname{vol}\left(S+[0, u] v_{\alpha}\right) \leq 4 u r$. Remark that the height of $S$ is $2 r$. Also, observe that for most $c \in(-r, r)$, the set $(B(x, r) \Delta B(y, r)) \cap H_{\alpha}(c)$ and the set $\left(S+[0, u] v_{\alpha}\right) \cap H_{\alpha}(c)$ both consist of two line segments, each of length $u$. It is not hard to see that the $c$ for which this is not the case are contained in $(-r,-r+u) \cup(r-u, r)$, so that

$$
4 u r \geq D_{r}(u, \alpha) \geq 4 u r-2 u^{2}
$$

This concludes the proof for the case $0<r<\frac{1}{2}$.
Let us now consider $\frac{1}{2} \leq r<\frac{1}{2} \sqrt{2}$. We will proceed in a similar manner. Let $S$ again denote the boundary of $B(x, r)$. But note that now, due to the toroïdal assumption, $S$ consists of four arcs of opening angle $\beta$ (see figure 7). We again wish

Figure 7: The "boundary" of $B(x, r)$ consists of four arcs of opening angle $\beta$.
to approximate $D_{r}(u, \alpha)$ by the area of $S+[0, u] v_{\alpha}$. Let $h(\alpha)$ be the length "counting multiplicities" of the projection of $S$ onto $\mathcal{L}\left(w_{\alpha}\right)$, i.e., $h(\alpha)=\int_{\mathbb{R}}\left|H_{\alpha}(c) \cap S\right| \mathrm{d} c$. We claim that

$$
D_{r}(u, \alpha)=u h(\alpha)+o(u)
$$

To see this, note that the length of $(B(x, r) \Delta B(y, r)) \cap H_{\alpha}(c)$ equals $u$ times the cardinality of $S \cap H_{\alpha}(c)$, unless one or more of the points in $S \cap H_{\alpha}$ are
a) within $u$ of the boundary of the square, or
b) within $u$ of another point of $S \cap H_{\alpha}$.

We have already seen that the error due to b) can be bounded by $2 u^{2}$. In order to bound the error due to a), let $S^{\prime}(u)$ be the set of all $s \in S$ for which a) is not the case. Clearly, as $u$ tends to 0 the length $l\left(S^{\prime}(u)\right)$ of $S^{\prime}(u)$ tends to the length $l(S)$ of $S$. We see that

$$
u h(\alpha)-u\left(l(S)-l\left(S^{\prime}(u)\right)\right)-2 u^{2} \leq D_{r}(u, \alpha) \leq u h(\alpha)
$$

Figure 8: The projections of the four arcs onto $\mathcal{L}\left(w_{\alpha}\right)$.
as required. Since $l(S)-l\left(S^{\prime}(u)\right)$ does not depend on $\alpha$ the error term is indeed uniform in $\alpha$.

It only remains to compute $h(\alpha)$ : for $\frac{\pi}{4}<\alpha \leq-\frac{\beta}{2}$, the length of the projections on $\mathcal{L}\left(w_{\alpha}\right)$ of the two arcs that contain the diagonal of the square is $r$ times $\left(\sin \left(\frac{\beta}{2}-\alpha\right)-\sin \left(-\frac{\beta}{2}-\alpha\right)\right)$, and the height of the other two arcs is $r$ times $\left(\sin \left(\frac{\pi}{2}-\frac{\beta}{2}-\alpha\right)-\sin \left(\frac{\pi}{2}+\frac{\beta}{2}-\alpha\right)\right)$. Thus, for $\frac{\pi}{4}<\alpha<-\frac{\beta}{2}$ we get

$$
\begin{aligned}
h(\alpha) & =2 r\left(\sin \left(\frac{\beta}{2}-\alpha\right)-\sin \left(-\frac{\beta}{2}-\alpha\right)+\sin \left(\frac{\pi-\beta}{2}-\alpha\right)-\sin \left(\frac{\pi+\beta}{2}-\alpha\right)\right) \\
& =2 r\left(\sin \left(\frac{\beta}{2}-\alpha\right)-\sin \left(-\frac{\beta}{2}-\alpha\right)+\cos \left(-\frac{\beta}{2}-\alpha\right)-\cos \left(\frac{\beta}{2}-\alpha\right)\right) \\
& =4 r \sin \left(\frac{\beta}{2}\right)(\cos (\alpha)-\sin (\alpha))
\end{aligned}
$$

For $-\frac{\beta}{2}<\alpha<\frac{\beta}{2}$, we obtain

$$
\begin{aligned}
h(\alpha) & =2 r\left(\sin \left(\frac{\beta}{2}-\alpha\right)-\sin \left(-\frac{\beta}{2}-\alpha\right)+2-\sin \left(\frac{\pi-\beta}{2}-\alpha\right)-\sin \left(\frac{\pi+\beta}{2}-\alpha\right)\right) \\
& =2 r\left(\sin \left(\frac{\beta}{2}-\alpha\right)-\sin \left(-\frac{\beta}{2}-\alpha\right)+2-\cos \left(-\frac{\beta}{2}-\alpha\right)-\cos \left(\frac{\beta}{2}-\alpha\right)\right) \\
& =4 r\left(1-\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \cos (\alpha)\right) .
\end{aligned}
$$

This concludes the proof.
It should be remarked that, for $r \in\left(0, \frac{1}{2}\right)$, the result can also be obtained in a relatively straightforward manner by explicitly computing $D_{r}(u, \alpha)=2 \pi r^{2}-$
$4 r^{2} \arccos \left(\frac{u}{2 r}\right)+2 u \sqrt{r^{2}-\frac{u^{2}}{4}}$ and considering the Taylor expansion of this expression. We have not chosen this route here because the method used fits better with the $\frac{1}{2} \leq r<\frac{1}{2} \sqrt{2}$ case.

Proof of Lemma 11: Notice that by symmetry, switching to polar coordinates

$$
\begin{aligned}
\mathbb{E} Z & =\binom{n}{2} \int_{[0,1]^{2}} \int_{B(x, r)}\left(1-D_{r}(x, y)\right)^{n-2} \mathrm{~d} y \mathrm{~d} x \\
& =\binom{n}{2} \int_{0}^{2 \pi} \int_{0}^{r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha \\
& =\binom{n}{2} 8 \int_{-\frac{\pi}{4}}^{0} \int_{0}^{r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha .
\end{aligned}
$$

Let us write

$$
F_{r}(\alpha):=\left\{\begin{array}{cl}
1 & \text { if } \quad r \leq \frac{1}{2} \\
\sin \left(\frac{\beta}{2}\right)(\cos (\alpha)-\sin (\alpha)) & \text { if } \quad r>\frac{1}{2} \text { and }-\frac{\pi}{4}<\alpha<-\frac{\beta}{2} \\
1-\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \cos (\alpha) & \text { if } \quad r>\frac{1}{2} \text { and }-\frac{\beta}{2} \leq \alpha \leq 0 .
\end{array}\right.
$$

Therefore, by Lemma 13 we have $D_{r}(u, \alpha)=4 u r F_{r}(\alpha)+o(u)$. Now, observe that $F_{r}(\alpha)>c$ for some $c=c(\epsilon)$ uniformly in all $r$ considered (recall that $r<\frac{1}{2} \sqrt{2}-\epsilon$ ). By Lemma 13, for every $\epsilon>0$ there exists a $\delta>0$ such that, if $u<\delta r$, then $(4-\epsilon) \operatorname{ur} F(\alpha)<D_{r}(u, \alpha)<(4+\epsilon) u r F_{r}(\alpha)$. Now notice that for $u>\delta r$ we have $D_{r}(u, \alpha)=\Omega\left(r^{2}\right)$.

$$
\begin{align*}
\int_{0}^{2 \pi} \int_{0}^{r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha= & \int_{0}^{2 \pi} \int_{0}^{\delta r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha \\
& +\int_{0}^{2 \pi} \int_{\delta r}^{r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha \\
\leq & \int_{0}^{2 \pi} \int_{0}^{\delta r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha  \tag{7}\\
& +\pi r^{2} e^{-\Omega\left(n r^{2}\right)}
\end{align*}
$$

We shall see later on that the last term on the last line is negligibly small compared to the first term on the last line, but first we must compute the first term in the last line. We have

$$
\begin{aligned}
\int_{0}^{2 \pi} \int_{0}^{\delta r}\left(1-D_{r}(u, \alpha)\right)^{n-2} 2 \pi u \mathrm{~d} u \mathrm{~d} \alpha & \leq \int_{0}^{\delta r} \exp [-(n-2)(4-\epsilon) u r F(\alpha)] 2 \pi u \mathrm{~d} u \mathrm{~d} \alpha \\
& =\int_{0}^{2 \pi} \frac{1}{((4-\epsilon)(n-2) r F(\alpha))^{2}} \int_{0}^{\delta(4-\epsilon) r^{2}(n-2)} e^{-v} v \mathrm{~d} v \mathrm{~d} \alpha \\
& \leq \frac{1+o(1)}{(4-\epsilon)^{2} n^{2} r^{2}} \int_{0}^{2 \pi} \frac{1}{F(\alpha)^{2}} \mathrm{~d} \alpha
\end{aligned}
$$

where we have used the substitution $v=(n-2)(4-\epsilon) \operatorname{urF}(\alpha)$ in the first equality and for the second equality we have used that $n r^{2}$ tends to infinity together with the fact that $\int_{0}^{\infty} t e^{-t} \mathrm{~d} t=1$.
On the other hand, we have

$$
\begin{aligned}
\int_{0}^{2 \pi} \int_{0}^{\delta r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha & \geq \int_{0}^{2 \pi} \int_{0}^{\delta r}(1-(4+\epsilon) u r F(\alpha))^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha \\
& \geq \int_{0}^{2 \pi} \int_{0}^{\delta r} e^{-(4+2 \epsilon) n u r F(\alpha)} u \mathrm{~d} u \mathrm{~d} \alpha \\
& =\frac{1+o(1)}{(4+2 \epsilon)^{2} n^{2} r^{2}} \int_{0}^{2 \pi} \frac{1}{F(\alpha)^{2}} \mathrm{~d} \alpha
\end{aligned}
$$

where the second inequality follows from the fact that $\ln (1-(4+\epsilon) \operatorname{ur} F(\alpha))=$ $-(4+\epsilon) \operatorname{urF} F(\alpha)+O\left(u^{2} r^{2}\right)$, so that (provided $\delta$ was chosen sufficiently small) $u \leq \delta r$
implies $(1-(4+\epsilon) \operatorname{urF}(\alpha)) \geq e^{-(4+2 \epsilon) u r F(\alpha)}$. The last line follows by previous computations. Now, notice that

$$
\frac{\pi r^{2} e^{-(4-\epsilon) \delta r^{2} n}}{r^{-2} n^{-2}}=\pi\left(n r^{2}\right)^{2} e^{-(4-\epsilon) \delta n r^{2}}=o(1)
$$

as $n r^{2}$ tends to infinity. So indeed, the second term on the last line of (7) is neglibly small compared to the first. Moreover,

$$
\int_{0}^{2 \pi} \int_{0}^{\delta r}\left(1-D_{r}(u, \alpha)\right)^{n-2} u \mathrm{~d} u \mathrm{~d} \alpha=\frac{1+o(1)}{16 n^{2} r^{2}} 8 \int_{-\frac{\pi}{4}}^{0} F(\alpha)^{-2} \mathrm{~d} \alpha
$$

In other words,

$$
\mathbb{E} Z=\frac{1+o(1)}{4 r^{2}} \int_{-\frac{\pi}{4}}^{0} F(\alpha)^{-2} \mathrm{~d} \alpha
$$

So it remains to determine $\int_{-\frac{\pi}{4}}^{0} F(\alpha)^{-2} \mathrm{~d} \alpha$. For $r \leq \frac{1}{2}$ this equals $\frac{\pi}{4}$, which gives the result. Thus, assume now that $r \in\left(\frac{1}{2}, \frac{1}{2} \sqrt{2}\right)$. Notice that

$$
\begin{aligned}
\int_{-\frac{\pi}{4}}^{-\frac{\beta}{2}} F(\alpha)^{-2} \mathrm{~d} \alpha & =\sin \left(\frac{\beta}{2}\right)^{-2} \int_{-\frac{\pi}{4}}^{-\frac{\beta}{2}}(\cos (\alpha)-\sin (\alpha))^{-2} \mathrm{~d} \alpha \\
& =\sin \left(\frac{\beta}{2}\right)^{-2}\left[\frac{\cos (\alpha)}{\cos (\alpha)-\sin (\alpha)}\right]_{-\frac{\pi}{4}}^{-\frac{\beta}{2}} \\
& =\sin \left(\frac{\beta}{2}\right)^{-2}\left(\frac{\cos \left(\frac{\beta}{2}\right)}{\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)}-\frac{1}{2}\right) .
\end{aligned}
$$

For convenience, we let $c:=\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right)^{-1}=\left(2-\frac{1}{2 r^{2}}\right)^{-\frac{1}{2}}$. We can now write

$$
\begin{aligned}
\int_{-\frac{\beta}{2}}^{0}(F(\alpha))^{-2} \mathrm{~d} \alpha= & \int_{-\frac{\beta}{2}}^{0}\left(1-\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \cos (\alpha)\right)^{-2} \mathrm{~d} \alpha \\
= & c^{2} \int_{-\frac{\beta}{2}}^{0}(c-\cos (\alpha))^{-2} \mathrm{~d} \alpha \\
= & c^{2}\left[\frac{2 \tan \left(\frac{\alpha}{2}\right)}{\left(c^{2}-1\right)\left((c+1) \tan \left(\frac{\alpha}{2}\right)^{2}+c-1\right)}+\frac{2 c \arctan \left(\sqrt{\frac{c+1}{c-1}} \tan \left(\frac{\alpha}{2}\right)\right)}{\left(c^{2}-1\right)^{\frac{3}{2}}}\right]_{-\frac{\beta}{2}}^{0} \\
= & \frac{c^{2}}{4\left(c^{2}-1\right)}\left(\frac{2 \tan \left(\frac{\beta}{4}\right)}{(c+1) \tan \left(\frac{\beta}{4}\right)^{2}+c-1}+\frac{2 c \arctan \left(\sqrt{\frac{c+1}{c-1}} \tan \left(\frac{\beta}{4}\right)\right)}{\sqrt{c^{2}-1}}\right) \\
= & \frac{1}{\sin (\beta)}\left(\frac{2\left(\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right) \tan \left(\frac{\beta}{4}\right)}{\left(1-\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)\right) \tan \left(\frac{\beta}{4}\right)^{2}+1+\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)}\right. \\
& \left.+\frac{2}{\sqrt{\sin (\beta)}} \arctan \left(\sqrt{\frac{\left(1-\cos \left(\frac{\beta}{2}\right)+\sin \left(\frac{\beta}{2}\right)\right)}{\left(1+\cos \left(\frac{\beta}{2}\right)-\sin \left(\frac{\beta}{2}\right)\right)}} \tan \left(\frac{\beta}{4}\right)\right)\right) .
\end{aligned}
$$

The statement follows.
Proof of Lemma 12: Let us again set $\mathcal{P}:=\binom{[n]}{2}$. For $P=\{i, j\} \in \mathcal{P}$, denote by $J(P)$ the indicator variable of the event that $\left\{X_{i}, X_{j}\right\}$ is a bad pair and set

$$
p_{i j}=\mathbb{E} J(\{i, j\})=\mathbb{P}\left(\left\{X_{i}, X_{j}\right\} \text { is a bad pair }\right) .
$$

For $\{i, j\},\{k, l\} \in \mathcal{P}$ let us also set

$$
p_{i j, k l}:=\mathbb{E} J(\{i, j\}) J(\{k, l\})=\mathbb{P}\left(\left\{X_{i}, X_{j}\right\},\left\{X_{k}, X_{l}\right\} \text { are both bad pairs }\right) .
$$

Notice that

$$
\begin{aligned}
\operatorname{Var}(Z)= & \sum_{P_{1}, P_{2} \in \mathcal{P}} \mathbb{E} J\left(P_{1}\right) J\left(P_{2}\right)-\mathbb{E} J\left(P_{1}\right) \mathbb{E} J\left(P_{2}\right) \\
= & \sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=2}}\left(\mathbb{E} J\left(P_{1}\right) J\left(P_{2}\right)-\mathbb{E} J\left(P_{1}\right) \mathbb{E} J\left(P_{2}\right)\right) \\
& +\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=1}}\left(\mathbb{E} J\left(P_{1}\right) J\left(P_{2}\right)-\mathbb{E} J\left(P_{1}\right) \mathbb{E} J\left(P_{2}\right)\right) \\
& +\sum_{\substack{P_{1}, P_{2} \in \mathcal{P},\left|P_{1} \cap P_{2}\right|=0}}\left(\mathbb{E} J\left(P_{1}\right) J\left(P_{2}\right)-\mathbb{E} J\left(P_{1}\right) \mathbb{E} J\left(P_{2}\right)\right) \\
= & \binom{n}{2}\left(p_{12}-p_{12}^{2}\right)+\binom{n}{2}(n-2)\left(p_{12,13}-p_{12}^{2}\right)+\binom{n}{2}\binom{n-2}{2}\left(p_{12,34}-p_{12}^{2}\right) .
\end{aligned}
$$

Observe that $\binom{n}{2}\left(p_{12}-p_{12}^{2}\right) \leq \mathbb{E} Z=o\left(r^{-4}\right)$ by Lemma 11. Let us now consider $p_{12,13}$. For $x_{1}, x_{2}, x_{3} \in \mathbb{R}^{2}$, denote by $\Phi\left(x_{1}, x_{2}, x_{3}\right)$ the probability that $\left\{X_{1}, X_{2}\right\}$ and $\left\{X_{1}, X_{3}\right\}$ are both bad pairs, given that $X_{1}=x_{1}, X_{2}=x_{2}, X_{3}=x_{3}$. We have

$$
\begin{aligned}
p_{12,13} & =\int_{[0,1]^{2}} \int_{B\left(x_{1}, r\right)} \int_{B\left(x_{1}, r\right)} \Phi\left(x_{1}, x_{2}, x_{3}\right) \mathrm{d} x_{3} \mathrm{~d} x_{2} \mathrm{~d} x_{1} \\
& =2 \int_{[0,1]^{2}} \int_{B\left(x_{1}, r\right)}^{\substack{B\left(x_{1}, r\right) \\
\left\|x_{1}-x_{3}\right\| \leq\left\|x_{1}-x_{2}\right\|}} \Phi\left(x_{1}, x_{2}, x_{3}\right) \mathrm{d} x_{3} \mathrm{~d} x_{2} \mathrm{~d} x_{1} \\
& \leq 2 \int_{[0,1]^{2}} \int_{B\left(x_{1}, r\right)} \int_{\left\|x_{1}-x_{3}\right\| \leq\left\|x_{1}-x_{2}\right\|}^{B\left(x_{1}, r\right)}\left(1-D_{r}\left(x_{1}, x_{2}\right)\right)^{n-3} \mathrm{~d} x_{3} \mathrm{~d} x_{2} \mathrm{~d} x_{1} \\
& =2 \int_{0}^{r} \pi u^{2}(1-\alpha(u))^{n-3} 2 \pi u \mathrm{~d} u .
\end{aligned}
$$

Here $D_{r}(x, y)$ is as in the proof of Lemma 11. Computations analogous to those in the previous lemma now give that

$$
\int_{0}^{r}(1-\alpha(u))^{n-3} u^{3} \mathrm{~d} u=(1+o(1)) \frac{1}{4^{4} r^{4} n^{4}} \int_{0}^{\infty} v^{4} e^{-v} \mathrm{~d} v=\Theta\left(r^{-4} n^{-4}\right)
$$

So we see that $\binom{n}{2}(n-2)\left(p_{12,13}-p_{12}^{2}\right)=O\left(n^{-1} r^{-4}\right)=o\left(r^{-4}\right)$.
Let us now consider $p_{12,34}$, and denote by $\Psi\left(x_{1}, x_{2}, x_{3}, x_{4}\right)$ the probability that $\left\{X_{1}, X_{2}\right\}$ and $\left\{X_{3}, X_{4}\right\}$ are both bad pairs given that $X_{1}=x_{1}, X_{2}=x_{2}, X_{3}=$ $x_{3}, X_{4}=x_{4}$. Let $A$ be the set of all $\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \in\left([0,1]^{2}\right)^{4}$ with $x_{2} \in B\left(x_{1}, r\right), x_{4} \in$ $B\left(x_{3}, r\right)$. Denote by $A_{1}$ the set of all $\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \in A$ with $\left\|x_{1}-x_{3}\right\|<100 r$ and set $A_{2}:=A \backslash A_{1}$. We have

$$
p_{12,34}=\int_{A} \Psi=\int_{A_{1}} \Psi+\int_{A_{2}} \Psi
$$

For $r \leq \frac{1}{4}$, the angle $\alpha$ is not relevant in $D_{r}(u, \alpha)$, so we will just write $D_{r}(u)$ here. If $\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \in A_{2}$ then $B\left(x_{1}, r\right) \Delta B\left(x_{2}, r\right)$ and $B\left(x_{3}, r\right) \Delta B\left(x_{4}, r\right)$ are disjoint, and consequently

$$
\begin{gathered}
\left(1-\operatorname{vol}\left(\left(B\left(x_{1}, r\right) \Delta B\left(x_{2}, r\right)\right) \cup\left(B\left(x_{3}, r\right) \Delta B\left(x_{4}, r\right)\right)\right)\right. \\
\leq \\
\left(1-D_{r}\left(x_{1}, x_{2}\right)\right)\left(1-D_{r}\left(x_{3}, x_{4}\right)\right) \\
= \\
\left(1-D_{r}\left(\left\|x_{1}-x_{2}\right\|\right)\right)\left(1-D_{r}\left(\left\|x_{3}-x_{4}\right\|\right)\right) .
\end{gathered}
$$

So we can write

$$
\begin{gathered}
\iiint \int_{A_{2}} \Psi\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \mathrm{d} x_{1} \mathrm{~d} x_{2} \mathrm{~d} x_{3} \mathrm{~d} x_{4} \\
\leq \\
\iiint \int_{A}\left(1-D_{r}\left(\left\|x_{1}-x_{2}\right\|\right)\right)^{n-4}\left(1-D_{r}\left(\left\|x_{3}-x_{4}\right\|\right)\right)^{n-4} \mathrm{~d} x_{1} \mathrm{~d} x_{2} \mathrm{~d} x_{3} \mathrm{~d} x_{4} \\
= \\
\left(\int_{0}^{r}\left(1-D_{r}(u)\right)^{n-4} 2 \pi u \mathrm{~d} u\right)^{2} \\
= \\
(1+o(1))\left(\frac{\pi}{8 r^{2} n^{2}}\right)^{2} \\
= \\
(1+o(1)) p_{12}^{2}
\end{gathered}
$$

reusing computations from the proof of Lemma 11 in the last two steps. On the other hand,

$$
\begin{gathered}
\int_{[0,1]^{2}} \int_{B\left(x_{1}, r\right)} \int_{B\left(x_{1}, 100 r\right)} \int_{B\left(x_{3}, r\right)} \Psi\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \mathrm{d} x_{4} \mathrm{~d} x_{3} \mathrm{~d} x_{2} \mathrm{~d} x_{1} \\
2 \int_{[0,1]^{2}} \int_{B\left(x_{1}, r\right)} \int_{B\left(x_{1}, 100 r\right)} \int_{\substack{B\left(x_{3}, r\right) \\
\left\|x_{3}-x_{4}\right\|<\| x_{1}-x_{2}| |}}^{\leq} \Psi\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \mathrm{d} x_{4} \mathrm{~d} x_{3} \mathrm{~d} x_{2} \mathrm{~d} x_{1} \\
2 \pi(100)^{2} r^{2} \int_{0}^{r} \pi u^{2}\left(1-D_{r}(u)\right)^{n-4} 2 \pi u \mathrm{~d} u \\
= \\
\Theta\left(r^{-2} n^{-4}\right) .
\end{gathered}
$$

We see that

$$
\binom{n}{2}\binom{n-2}{2}\left(p_{12,34}-p_{12}^{2}\right)=\binom{n}{2}\binom{n-2}{2}\left(\Theta\left(r^{-2} n^{-4}\right)+o(1) p_{12}^{2}\right)=o\left(r^{-4}\right)
$$

This shows that $\operatorname{Var}(Z)=o\left(r^{-4}\right)$, as required.
It now remains to prove Theorem 5 for fixed $r \in\left(0, \frac{1}{2} \sqrt{2}\right)$. We will prove the following proposition.

Proposition 14 For fixed $r \in\left(0, \frac{1}{2} \sqrt{2}\right)$, the number $Z$ of bad pairs satisfies

$$
Z \rightarrow \operatorname{Po}(\mu(r)) \text { in distribution. }
$$

In particular,

$$
\mathbb{P}(Z=0) \rightarrow e^{-\mu(r)}
$$

As it turns out, the fixed $r$ case has already been considered by Agarwal and Spencer [1] in a different setting. They proved Proposition 14 for $r<\frac{1}{10}$ and our proof is essentially the same as theirs, but we include it for completeness.

Proof of Proposition 14: Let us set $\rho=\rho(n):=\frac{\ln ^{2} n}{n}$. Let $Y$ be the number of bad pairs $X_{i}, X_{j}$ with $\left\|X_{i}-X_{j}\right\|<\rho$. Notice that

$$
\begin{equation*}
\mathbb{P}(Z \neq Y) \leq \mathbb{E}(Z-Y)=O\left(n^{2} e^{\Omega\left(\ln ^{2} n\right)}\right)=o(1) \tag{8}
\end{equation*}
$$

Here we have used that $D_{r}(u, \alpha)=\Theta(u)$. Recall that $(m)_{k}=m(m-1) \ldots(m-k+1)$. We shall show that, for all $k$,

$$
\begin{equation*}
\mathbb{E}(Y)_{k}=(1+o(1)) \mu(r)^{k} \tag{9}
\end{equation*}
$$

This will prove that $Y$ - and hence also $Z$ - is approximately $\operatorname{Po}(\mu(r))$-distributed, as all the moments of $Y$ tend to the corresponding moments of the $\operatorname{Po}(\mu(r))$, and the result will follow. This method is sometimes called Brunn's sieve, see for instance [2]. We shall proceed by induction on $k$. The case $k=1$ has already been taken care of by Lemma 11 together with (8), so let us assume that (9) holds for $k-1$, with $k \geq 2$. If $\mathcal{P}=\left(\underset{2}{\left\{X_{1}, \ldots, X_{n}\right\}}\right)$ denotes all pairs of nodes and for $P \in \mathcal{P}$ we denote by $J(P)$ the event that $P$ is a bad pair and the points of the pair are at distance $<\rho$, then

$$
\begin{equation*}
\mathbb{E}(Y)_{k}=\sum_{P_{1} \in \mathcal{P}} \sum_{P_{2} \in \mathcal{P} \backslash\left\{P_{1}\right\}} \ldots \sum_{P_{k} \in \mathcal{P} \backslash\left\{P_{1}, \ldots, P_{k-1}\right\}} \mathbb{P}\left(J\left(P_{1}\right), \ldots, J\left(P_{k}\right)\right) . \tag{10}
\end{equation*}
$$

First notice that the contribution by terms with $P_{i} \cap P_{j} \neq \emptyset$ for some $i \neq j$ is small:

$$
\begin{gathered}
\sum_{P_{1} \in \mathcal{P}} \sum_{P_{2} \in \mathcal{P} \backslash\left\{P_{1}\right\}} \cdots \sum_{\substack{P_{k} \in \mathcal{P} \backslash\left\{P_{1}, \ldots, P_{k-1}\right\} \\
\left|P_{k-1} \cap P_{k}\right|=1}} \mathbb{P}\left(J\left(P_{1}\right), \ldots, J\left(P_{k}\right)\right) \\
\leq \\
\sum_{P_{1} \in \mathcal{P}} \sum_{P_{2} \in \mathcal{P} \backslash\left\{P_{1}\right\}} \cdots \sum_{\substack{P_{k} \in \mathcal{P} \backslash\left\{P_{1}, \ldots, P_{k-1}\right\} \\
\left|P_{k-1} \cap P_{k}\right|=1}} \mathbb{P}\left(J\left(P_{1}\right), \ldots, J\left(P_{k-1}\right)\right) \pi\left(\frac{\ln ^{2} n}{n}\right)^{2} \\
\leq \\
\sum_{P_{1} \in \mathcal{P}} \sum_{P_{2} \in \mathcal{P} \backslash\left\{P_{1}\right\}} \cdots \sum_{P_{k-1} \in \mathcal{P} \backslash\left\{P_{1}, \ldots, P_{k-2}\right\}} \mathbb{P}\left(J\left(P_{1}\right), \ldots, J\left(P_{k-1}\right)\right) n \pi\left(\frac{\ln ^{2} n}{n}\right)^{2} \\
= \\
(1+o(1)) \mu(r)^{k-1} n \pi\left(\frac{\ln ^{2} n}{n}\right)^{2} \\
= \\
o(1) .
\end{gathered}
$$

Here we have used the induction hypothesis. For $i=1, \ldots, k$ let us set $A(i):=$ $\bigcap_{j=1}^{i} J\left(\left\{X_{2 j-1}, X_{2 j}\right)\right.$. By the previous we have

$$
\begin{aligned}
\mathbb{E}(Y)_{k} & =\binom{n}{2}\binom{n-2}{2} \ldots\binom{n-2(k-1)}{2} \mathbb{P}(A(k))+o(1) \\
& =(1+o(1)) n^{2 k} 2^{-k} \mathbb{P}(A(k))+o(1)
\end{aligned}
$$

Next, for $\epsilon>0$ fixed,

$$
\begin{gathered}
n^{2 k} 2^{-k} \mathbb{P}\left(A(k) \text { and }\left\|X_{2 i}-X_{2 j}\right\|<n^{-\frac{1}{2}-\epsilon} \text { for some } 1 \leq i<j \leq k\right) \\
\leq \\
n^{2 k} 2^{-k}\binom{k}{2} \mathbb{P}(A(k-1)) \pi^{2}\left(n^{-\frac{1}{2}-\epsilon}\right)^{2}\left(n^{-\frac{1}{2}-\epsilon}+\rho\right)^{2} \\
= \\
\binom{k}{2}(1+o(1)) \mu(r)^{k-1} \pi^{2} n^{-2-4 \epsilon+o(1)}=o(1) .
\end{gathered}
$$

Consequently, we also have

$$
\begin{equation*}
\mathbb{E}(Y)_{k}=(1+o(1)) n^{2 k} 2^{-k} \mathbb{P}(B(k))+o(1) \tag{11}
\end{equation*}
$$

where $B(i)$, for $i \in\{1, \ldots, k\}$, denotes the event that $A(i)$ holds and $\left\|X_{2 j}-X_{2 j^{\prime}}\right\|>$ $n^{-\frac{1}{2}-\epsilon}$ for every $j, j^{\prime} \in\{1,2, \ldots, i\}$ with $j<j^{\prime}$. For $x_{1}, \ldots, x_{2 k} \in[0,1]^{2}$, let us set

$$
D_{r}\left(x_{1}, \ldots, x_{2 k}\right)=\operatorname{vol}\left(\bigcup_{i=1}^{k}\left(B\left(x_{2 i-1}, r\right) \Delta B\left(x_{2 i}, r\right)\right)\right)
$$

We now claim that if $\left\|x_{2 i-1}-x_{2 i}\right\|<\frac{\ln ^{2} n}{n}$ for every $i \in\{1,2, \ldots, k\}$ and $\left\|x_{2 i}-x_{2 j}\right\|>$ $n^{-\frac{1}{2}-\epsilon}$ for all $i, j \in\{1,2, \ldots, k\}$ with $i<j$, then

$$
\begin{equation*}
D_{r}\left(x_{1}, \ldots, x_{2 k}\right)=\sum_{i=1}^{k} D_{r}\left(x_{2 i-1}, x_{2 i}\right)+o\left(n^{-1}\right) \tag{12}
\end{equation*}
$$

To see this consider $C=\left(B\left(x_{1}, r\right) \Delta B\left(x_{2}, r\right)\right) \cap\left(B\left(x_{3}, r\right) \Delta B\left(x_{4}, r\right)\right)$ under the assumptions that $\left\|x_{1}-x_{2}\right\|,\left\|x_{3}-x_{4}\right\|<\rho$ and $\left\|x_{2}-x_{4}\right\|=l \geq n^{-\frac{1}{2}-\epsilon}$. Then $C$ is contained in the intersection of the two annuli $A_{2}:=\left\{y: r<\left\|y-x_{2}\right\|<r+\rho\right\}$ and $A_{4}:=\left\{y: r<\left\|y-x_{4}\right\|<r+\rho\right\}$, see figure 9 below. We will use the bound

Figure 9: Bounding $\operatorname{vol}\left(A_{2} \cap A_{3}\right)$.
$\operatorname{vol}\left(A_{2} \cap A_{3}\right) \leq 2 \frac{\alpha_{2}}{2 \pi} \operatorname{vol}\left(A_{2}\right)$ with $\alpha_{1}, \alpha_{2}$ as shown in figure 9 . Now, the angles $\alpha_{1}, \alpha_{2}$ satisfy

$$
\begin{aligned}
\cos \left(\alpha_{1}\right)=\frac{l_{2}}{r+\rho}, & \cos \left(\alpha_{1}+\alpha_{2}\right)=\frac{l_{1}}{r} \\
\sin \left(\alpha_{1}\right)=\frac{h}{r+\rho}, & \sin \left(\alpha_{1}+\alpha_{2}\right)=\frac{h}{r} .
\end{aligned}
$$

where $h, l_{1}, l_{2}$ are as in figure 9. In particular,

$$
\begin{equation*}
l=l_{1}+l_{2}, \quad h^{2}=r^{2}-l_{1}^{2}=(r+\rho)^{2}-l_{2}^{2} \tag{13}
\end{equation*}
$$

Notice that $l_{1}$ may be negative (this can happen for small $l$ ), but this does not pose any limitation for our computations. First, assume that $l_{2} \geq \frac{1}{2} r$. The Taylor expansion of $\sin (x)$ around $x=\alpha_{1}$ gives

$$
\frac{\rho h}{r(r+\rho)}=\sin \left(\alpha_{1}+\alpha_{2}\right)-\sin \left(\alpha_{1}\right)=\cos \left(\alpha_{1}\right) \alpha_{2}+O\left(\alpha_{2}^{2}\right)=\frac{l_{2}}{r+\rho} \alpha_{2}+O\left(\alpha_{2}^{2}\right)
$$

Since $\frac{1}{2} r \leq l_{2} \leq r+\rho$ and $h \leq r$, we see that is this case we must have $\alpha_{2}=O(\rho)=$ $O\left(n^{-1+o(1)}\right)$.

Now suppose that $l_{2} \leq \frac{1}{2} r$. The Taylor expansion of $\cos (x)$ around $x=\alpha_{1}$ gives

$$
\begin{aligned}
\frac{l_{1}}{r}-\frac{l_{2}}{r+\rho}=\frac{\rho l_{1}-r\left(l_{2}-l_{1}\right)}{r(r+\rho)} & =\cos \left(\alpha_{1}+\alpha_{2}\right)-\cos \left(\alpha_{1}\right) \\
& =-\sin \left(\alpha_{1}\right) \alpha_{2}+O\left(\alpha_{2}^{2}\right) \\
& =-\frac{h}{r+\rho} \alpha_{2}+O\left(\alpha_{2}^{2}\right) .
\end{aligned}
$$

Observe that $h=\sqrt{(r+\rho)^{2}-l_{2}^{2}} \geq r \frac{1}{2} \sqrt{3}$ and that, by equations (13),

$$
l\left(l_{2}-l_{1}\right)=l_{2}^{2}-l_{1}^{2}=(r+\rho)^{2}-r^{2}=2 \rho r+\rho^{2}
$$

Hence, $l_{2}-l_{1}=O\left(\frac{\rho}{l}\right)=O\left(n^{-\frac{1}{2}+\epsilon+o(1)}\right)$, since $l \geq n^{-\frac{1}{2}-\epsilon}$. Thus this time we have $\alpha_{2}=O\left(n^{-\frac{1}{2}+\epsilon+o(1)}\right)$. Consequently, $\operatorname{vol}\left(A_{2} \cap A_{3}\right) \leq \frac{\alpha_{2}}{\pi} \operatorname{vol}\left(A_{2}\right)=O\left(n^{-\frac{1}{2}+\epsilon+o(1)} \rho\right)=$ $O\left(n^{-\frac{3}{2}+\epsilon+o(1)}\right)$. This proves (12).

Now let $x_{2}, x_{4}, \ldots, x_{2 k} \in[0,1]^{2}$ be such that $\left\|x_{2 j}-x_{2 i}\right\|>n^{-\frac{1}{2}-\epsilon}$ for all $i, j \in$
$\{1,2, \ldots, k\}$ with $i<j$. Then

$$
\begin{gathered}
\mathbb{P}\left(B(k) \mid X_{2}=x_{2}, \ldots, X_{2 k}=x_{2 k}\right) \\
= \\
= \\
\int_{B\left(x_{2}, \rho\right)} \ldots \int_{B\left(x_{2 k}, \rho\right)}\left(1-D_{r}\left(x_{1}, \ldots, x_{2 k}\right)\right)^{n-2 k} \mathrm{~d} x_{1} \mathrm{~d} x_{3} \ldots \mathrm{~d} x_{2 k-1} \\
= \\
\int_{B\left(x_{2}, \rho\right)} \ldots \int_{B\left(x_{2 k}, \rho\right)}\left(1-\sum_{i=1}^{k} D_{r}\left(x_{2 i-1}, x_{2 i}\right)+o\left(n^{-1}\right)\right)^{n-2 k} \mathrm{~d} x_{1} \ldots \mathrm{~d} x_{2 k} \\
= \\
\int_{0}^{2 \pi} \int_{0}^{\rho} \ldots \int_{0}^{2 \pi} \int_{0}^{\rho}\left(1-\sum_{i=1}^{k} D_{r}\left(u_{i}, \alpha_{i}\right)+o\left(n^{-1}\right)\right)^{n-2 k} u_{1} \ldots u_{k} \mathrm{~d} u_{1} \mathrm{~d} \alpha_{1} \ldots \mathrm{~d} u_{k} \mathrm{~d} \alpha_{k} \\
\\
(1+o(1)) \int_{0}^{2 \pi} \int_{0}^{\rho} \ldots \int_{0}^{2 \pi} \int_{0}^{\rho} \exp \left[-(1+o(1)) \sum_{i=1}^{k} n D_{r}\left(u_{i}, \alpha_{i}\right)+o(1)\right] u_{1} \ldots u_{k} \mathrm{~d} u_{1} \mathrm{~d} \alpha_{1} \ldots \mathrm{~d} u_{k} \mathrm{~d} \alpha_{k} \\
\\
= \\
(1+o(1))\left(\int_{0}^{2 \pi} \int_{0}^{\rho} \exp \left[-(1+o(1)) \sum_{i=1}^{k} n D_{r}(u, \alpha)+o(1)\right] u \mathrm{~d} u \mathrm{~d} \alpha\right)^{k} \\
\\
= \\
(1+o(1))\left(\frac{2 \mu(r)}{n^{2}}\right)^{k}
\end{gathered}
$$

where the last three lines follow by computations as in Lemma 11. Thus, setting $W:=\left\{\left(x_{2}, x_{4}, \ldots, x_{2 k}\right) \in\left([0,1]^{2}\right)^{k}:\left\|x_{2 i}-x_{2 j}\right\|>n^{-\frac{1}{2}-\epsilon}\right.$ for all $\left.1 \leq i<j \leq k\right\}$, we also have

$$
\begin{aligned}
\mathbb{P}(B(k)) & =\int \ldots \int_{W} \mathbb{P}\left(B(k) \mid X_{2}=x_{2}, \ldots, X_{2 k}=x_{2 k}\right) \mathrm{d} x_{2} \mathrm{~d} x_{4} \ldots \mathrm{~d} x_{2 k} \\
& =(1+o(1))\left(\frac{2 \mu(r)}{n^{2}}\right)^{k},
\end{aligned}
$$

since the $2 k$-dimensional volume $\operatorname{vol}(W)$ of $W$ is $1+o(1)$. Combining this with (11) gives the result.

## 4 Conclusion

We addressed in this paper, via the notion of identifying codes, the question of a location-detection system for a set of sensors whose communication area is modelled by disks. Therefore, we considered the class of unit disk graphs. We first extended a previous complexity result from the class of bipartite graphs to the class of planar bipartite unit disk graphs. Our second result concerns random unit disk graphs. We showed that, asymptotically almost surely, an identifying code does not exist for such a graph, if the radius $r$ of the disks is such that $n r^{2} \gg \frac{1}{n}$ and $r=o(1)$. For fixed $r>0$, the probability that an identifying code exists is always bounded away from one, so that it does not seem to make a lot of sense to pursue this line of research further. In contrast, for the Erdős-Rényi model of random graphs, it has been shown that if $p$ and $1-p$ both are at least $\frac{4 \log \log n}{\log n}$, then an identifying code exists whp. [8]. Notice this includes all fixed $p \in(0,1)$. Hence one can then - as the authors of [8]
did — proceed to investigate the size of the smallest identifying code. In the case of random unit disk graphs an identifying code is only guaranteed when $n r^{2} \ll \frac{1}{n}$, and in this case the only such code is the entire vertex set. Of course, one might look for the size of a smallest identifying code in the other cases, if we condition on the event that such a code exists.

Another topic of research would be to slightly relax the definition of the code so that it always exists. For instance, a location code is the same as an identifying code, except that it does not need to identify the vertices belonging to the code. This notion could still be useful for real situations, and lead to interesting results.
